

NUCLEOTIDE SEQUENCES OF HIV-1 GROUP  
(OR SUBGROUP) O RETROVIRAL ANTIGENS

5           The invention relates to the antigens obtained  
by expression of nucleotide sequences or by chemical  
synthesis, for example using Applied Biosystems brand  
synthesizers, present in HIV-1 group (or subgroup) O  
variants and more particularly the antigens  
10 corresponding to those which may be isolated from viral  
particles. By way of example of HIV-1 viruses of the  
subgroup O, reference is made to the HIV-1<sub>(VAU)</sub> isolate  
and to the HIV-1<sub>(DUR)</sub> isolate.

15           The invention also relates to monoclonal or  
polyclonal antibodies induced by these antigens.

          The invention also relates to cloned DNA  
sequences either having sequence analogy or  
complementarity with the genomic RNA of the  
abovementioned virus. The invention also relates to  
20 processes for the preparation of these cloned DNA  
sequences. The invention also relates to polypeptides  
containing amino acid sequences coded for by the cloned  
DNA sequences.

25           Furthermore, the invention relates to  
applications of the antigens mentioned above to the in

vitro detection in at-risk individuals of certain forms of AIDS and, as regards some of them, to the production of immunogenic compositions and vaccinating compositions against this retrovirus. Similarly, the invention relates to applications of the abovementioned antibodies for the same purposes and, for some of them, to their application to the production of active principles for medicinal products against this human AIDS.

10           The invention also relates to the application of the cloned DNA sequences and of the polypeptides obtained from these sequences as probes or primers for gene amplification, in diagnostic kits.

15           The invention also relates to antigenic compositions which may be obtained by chemical synthesis or by expression in a recombinant cell host and which allow the diagnosis of an infection due to a human retrovirus of HIV type independently of the HIV-1 or HIV-2 subtype. Such compositions comprise at least  
20   one peptide chosen from the antigenic peptides common to the HIV-1, HIV-2, HIV-1<sub>(DUR)</sub> and HIV-1<sub>(VAU)</sub> viruses or variants of the antigenic peptides possessing similar immunogenic characteristics.

25           The invention is also directed toward compositions which allow the specific diagnosis of an infection due to a human retrovirus of HIV-1 type, more particularly HIV-1, group M, HIV-2 or HIV-1 group (or subgroup) O and comprising at least one antigenic peptide specific for the HIV-1 virus, an antigenic  
30   peptide specific for the HIV-2 virus and an antigenic peptide specific for the HIV-1 group (or subgroup) O virus or variants of these antigenic peptides possessing similar immunogenic characteristics. More particularly, the antigenic peptides are derived  
35   from the envelope protein of HIV-1 group M and HIV-2 and HIV-1 group (or subgroup) O viruses.

The invention is moreover directed toward a peptide allowing detection of anti-HIV antibodies which the peptides of the prior art did not always make it possible to detect, based in particular on the discovery of a new HIV-1 strain: HIV-1 DUR. The antiserum directed against it does not always have reactivity with the peptides of the consensus HIV as it is used nowadays. The term "consensus HIV" refers to the regions which are conserved between isolates and whose demonstration is essential to the design of diagnostic reagents or vaccines, and whose mutations impart resistance to antiviral medicinal products. The term "peptide" used in the present text defines both oligopeptides and polypeptides.

#### State of the art

Two types of human immunodeficiency virus (HIV) which have responsibility for the development of an LAS or AIDS have been isolated and characterized. A first virus, known as LAV-1 or HIV-1, was isolated and described in GB patent application 8324,800 and patent application EP 84401,834 of 14/09/1984. This virus was also described by F. Barré-Sinoussi et al. in Science (1983), 220, 868-871.

The type 2 HIV retrovirus belongs to a separate class and has only a limited immunological relationship with type 1 HIV retroviruses. HIV-2 retroviruses have been described in European patent application No. 87,400,151,4 published under the number 239,425.

The HIV-1 retrovirus is the most common and its presence is predominant in several regions worldwide. As regards the HIV-2 retrovirus, it is most often found in West Africa, although its propagation outside this region has recently been documented by Grez et al., (1994) J. Virol. 68, 2161-2168.

The totality of primate immunodeficiency lentiviruses, comprising the type 1 and type 2 human immuno-

deficiency viruses as well as several types of non-human primate viruses, is increasing in size and complexity. The most common of these viruses, HIV-1, is currently spreading in the form of a worldwide epidemic and is responsible for a major public health problem. Shortly after the identification and molecular characterization of this virus, it was recognized as being highly variable, and currently comprises several subtypes (Myers, 1994, Louwagie, et al. 1993, Louwagie et al. 1992, Myers, G. (1994) HIV-1 subtypes and phylogenetics trees. In: Human Retrovirus and AIDS 1994; Myers, G., Korber, B., Wain-Hobson, S., Smith, R.F. and Pavlakis, G.N., Eds. Los Alamos National Laboratory, Los Alamos, NM. III-2 - III-9.). This differentiation of subtypes is mainly based on the divergence of the gag and env genes. At least 6 subtypes have been identified, designated A to F, but several are still likely to emerge from the ongoing extensive worldwide survey on the isolates of HIV-1. It has been found that these various subtypes are equidistant from each other, in a phylogenetic profile termed star phylogeny, which suggests that the various HIV-1 subtypes might have evolved and diverged synchronously from a common ancestor.

Recently, two separate viruses of this group of HIV-1 viruses were isolated and characterized. These two viruses were obtained from patients living in Cameroon, in West Central Africa (Gürtler, et al. 1994, Vanden Heasevelde, et al. 1994). Their sequence, more particularly the sequence of their env (envelope) gene, shows clearly that these viruses belong to a separate category of HIV-1-related viruses, referred to as HIV-1 group O (Nkengasong et al., 1993).

However, the diversity of the isolates within this group of HIV-1-related viruses is not known, and its propagation outside Africa has not been documented.

A general constraint, in the development of HIV serological tests, is to avoid both falsely positive - or falsely negative - results while at the same time retaining or improving the sensitivity in terms of  
5 detection of seropositivity which the previous tests allow.

Tests based on the use of consensus peptide(s), essentially derived from the "env" gene, were considered as an almost ideal solution until the  
10 discovery of the HIV-1-O variant brought to light the possibility of falsely negative results (Genomic cloning and complete sequence analysis of a highly divergent African human immunodeficiency virus isolate. J. Virol. 1994; 68: 1586-96; a new subtype of human  
15 immunodeficiency virus type 1 (MPV-5180) from Cameroon. J. Virol. 1994; 68: 1581-85).

The non-reactivity of certain tests with "env" peptide antigen, in patients nonetheless exhibiting certain clinical syndromes characteristic of AIDS or  
20 lymphadenopathy syndromes which occasionally precede them, is, at the present time, occasionally attributed to an infection of the HIV-1-O group (HIV-1/HIV-2 seronegativity in HIV-1 subtype O infected patients, Lancet 1994; 343: 1393-94; New HIV-1 subtype in  
25 Switzerland. Lancet 1994; 344: 270-71).

#### Description of the invention

The aim of the present invention is to provide diagnostic laboratories with means, in particular  
30 specific peptides, allowing a detection of anti-HIV antibodies which were hitherto liable to be undetected. The invention also relates to mixtures of peptides obtained from HIV-1 DUR and of corresponding peptides from other HIVs, so as to avoid potential "false  
35 negative" results.

The invention moreover relates to a process of detection and of discrimination, in a biological

sample, between antibodies characteristic of an HIV-1-M type retrovirus and antibodies characteristic of an HIV-1 group (or subgroup) O retrovirus.

5 The invention stems from observations made on a seropositive woman who had stayed in the Cameroon and who had revealed an atypical serological reactivity, in the course of several tests of screening for HIV infection, these tests having been confirmed by "Western blot" techniques.

10 On account of this atypical serological reactivity, in particular the lack of reactivity to certain third-generation tests, even modified for the O type, the inventors considered it interesting to carry out sequencing of certain parts of the genome of this  
15 HIV-1 DUR strain, more specifically of the GAG and ENV genes.

However, gene amplifications by PCR using primers obtained from the M group and known primers from the O group were unsuccessful for the parts coding  
20 for the V3 loop of gp120, and for the immunodominant region of gp41. Only the GAG region could be amplified using primers known in the prior art (Loussert-Ajaka I, Lancet 1994; 343: 1393). Another aim of the present invention is consequently to determine primers capable  
25 of overcoming this problem.

Partial sequences of the glycoproteins gp41 and gp120 were determined, along with capsid proteins (GAG gene), from lymphocyte DNA and from viral cultures, indicating that this HIV-1 DUR strain belongs in part  
30 to the HIV-1-O group, and that it differs considerably from the M group, more particularly as regards gp41 and gp120.

Thus, it was possible to demonstrate, more particularly as regards the GAG sequence of HIV-1<sub>(DUR)</sub>,  
35 the existence of consensus sequences in the O group, in several regions, which are distinct from the consensus sequences of the M group in the same regions.

Cloning of the sequences coding for the GAG, gp41 and gp120 fragments of HIV-1<sub>(DUR)</sub> was carried out in a Bluescript® plasmid containing a PST1 site. The amplification products were cloned either according to  
5 the standard techniques using T3 and T7 universal primers, or directly sequenced by using the primers of the preceding amplification. The sequences were then determined with the Applied Biosystems 373A automated sequencer (ESGS Montigny le Bretonneux, France).

10 Within the context of the present invention, the inventors have isolated and sequenced the env gene from an O group isolate, HIV-1<sub>(VAU)</sub>, obtained from a French patient who had never traveled outside Europe and who died of AIDS in 1992. According to its envelope  
15 sequence, HIV-1<sub>(VAU)</sub> is related to two recently characterized Cameroonian viruses HIV<sub>ANT70</sub> and HIV<sub>MVP5180</sub>. Phylogenetic analysis of the env sequences reveals that the three viruses appear to constitute a separate group, which will be referred to herein as HIV-1 group  
20 O. The isolation of HIV-1<sub>(VAU)</sub> from this patient also indicates that a degree of propagation of HIV-1 group O has already occurred outside Africa.

#### Isolation of the HIV-1<sub>(VAU)</sub> virus

25 HIV-1<sub>(VAU)</sub> was isolated in 1992 from a 41-year-old French patient suffering from AIDS. This patient exhibited, in 1986, a severe leuconeutropenia associated with a carcinoma of the uterine cervix. However, she gradually showed signs of opportunistic infections, with  
30 a reduction in the number of circulating CD4<sup>+</sup> T cells and she died of AIDS in 1992. Anti-HIV-1 antibodies were first detected by ELISA (Elavia, Sanofi Diagnostics Pasteur and Abbott test) in 1990.

The patient had never traveled outside Europe,  
35 had not used intravenous medicinal products and had not received any known blood transfusion. No sexual partner of African origin has been identified. She gave birth to

a healthy child in 1971, but a son, born in 1980, died at the age of one following a clinical episode highly suggestive of neonatal AIDS. Her third child, born in 1983, and her husband are currently in good health and not infected.

The isolation of the virus was carried out in the following manner: the CD8<sup>+</sup> cells present in the PBMCs (peripheral blood lymphocytes) of the patient were removed using beads coated with IOT8 antibodies (Immunotech). These remaining PBMCs were stimulated with PHA, then cocultured with CD8-depleted PBMCs obtained from a healthy donor and stimulated with PHA. Viral growth in the coculture was monitored by assaying the reverse transcriptase (RT) activity of the supernatant and by ELISA test of the HIV-1 p24 (diagnostic kit marketed by DuPont de Nemours). The virus obtained from the initial coculture was subjected to several passages in CD8-depleted and PHA-stimulated PBMC cultures. Several attempts were made to infect, with the HIV-1<sub>(VAU)</sub>, various transformed cell lines, including MT4 cells (Harada, et al. 1985) and CEM cells (Rey, et al. 1989), as well as the Hela-CD4-LTRLacZ cell line P4-2 (Clavel and Charneau 1994).

#### Biological characterization of HIV-1<sub>(VAU)</sub>

Two weeks after coculturing the patient's CD8-depleted, PHA-stimulated PBMCs with similar cells from a healthy donor, the production of virus was detected in the form of an RT activity peak in the culture supernatant. This virus could then be subjected to serial passages on CD8-depleted, PHA-stimulated normal PBMCs. In Figure 1, plate A represents the production of HIV-1<sub>(VAU)</sub> in infected PBMC culture supernatants, checked by RT assay (filled circles) and HIV-1 p24 antigen capture ELISA (empty circles). The concentration of HIV-1 p24 is expressed in ng/ml and the RT activity in cpm/μl. In plate B, the same experiment

was carried out with a standard primary HIV-1 isolate from an AIDS patient.

Although the growth of HIV-1<sub>(VAU)</sub> was easily detected by RT assay, the detection of virus in the culture supernatants by HIV-1 p24 ELISA (DuPont) was substantially less sensitive. Figure 1 shows the comparison between the profiles of productive infection of PBMCs either with HIV-1<sub>(VAU)</sub> or with a primary HIV-1 isolate from an AIDS patient, assayed by RT or p24. For equivalent quantities of particles, determined by assay of RT activity in the supernatants assayed, approximately 25 times less p24 was detected in the case of HIV-1<sub>(VAU)</sub> than in the case of the other HIV-1 isolate. The difference may be due to the fact that the monoclonal antibody specific for HIV-1 p24, which is used to coat the ELISA plates, has only a weak affinity for the gag products of HIV-1<sub>(VAU)</sub>.

Several negative attempts were made to propagate HIV-1<sub>(VAU)</sub> on transformed human T cell lines sensitive to HIV-1. In particular, cocultures between PBMCs infected with HIV-1<sub>(VAU)</sub> and either MT4 cells or CEM cells did not lead to propagation of the virus. It was also found that this virus was not capable of infecting CD4<sup>+</sup> HeLa cells (P4-2) (Clavel and Charneau 1994) carrying a lacZ gene inducible by the tat gene. Likewise, no replication of HIV-1<sub>(VAU)</sub> could be detected in activated peripheral blood lymphocytes from several chimpanzees.

Analysis of the HIV-1<sub>(VAU)</sub> envelope sequence, which will be described in detail later, and its comparison with that of the two recently described Cameroonian isolates indicate that all three viruses belong to the same group of HIV-1-related viruses. Furthermore, this comparison indicates that these three variants of the virus are approximately phylogenetically equidistant from each other. Consequently, each of the three virus variants constitutes on its own a distinct subtype of their group, which is now called HIV-1 group

O. This group is different from the group of other HIV-1 isolates, identified up until now, which the inventors call here HIV-1, group M.

5 The appearance of this new group poses the question of its origin: did group O evolve from group M viruses (or conversely) or does each group have a different history? The inventors think that, insofar as both group M and group O have a similar internal divergence profile, it is likely that they each  
10 correspond to the diversification of distinct viral ancestors in distinct human populations. It is not possible to assess from the phylogenetic and virological data currently available whether the ancestor of either of the two groups affected humans naturally or was  
15 introduced into humans from other species. The only virus similar to HIV-1 present in a nonhuman primate is the SIVCPZGAB isolate (Huet, et al. 1990), isolated from a chimpanzee apparently infected naturally, which is clearly different both from group M and from group O,  
20 and for which no human equivalent has been found. It is unlikely that the group O viruses evolved recently from a chimpanzee virus insofar as HIV-1<sub>(VAN)</sub> has not succeeded in replicating in chimpanzee lymphocytes.

Why does the group O epidemic appear only now,  
25 some 15 to 20 years later than group M? There are three possible explanations: firstly, the introduction of the ancestor of the group O viruses into humans is thought to have occurred more recently than that of group M; secondly, it is possible that group M was allowed to  
30 spread earlier compared with group O because of different social conditions in their region of origin; and thirdly, the group O viruses could have a lower capacity for transmission compared with that of the group M viruses. It has been proposed that such a  
35 property explains the absence of significant worldwide propagation of HIV-2, for which a smaller viral load in infected subjects is linked to reduced transmissibility

(De Cock, et al. 1993). In this regard, although no data are available on the viral load in patients infected with an HIV-1 group O, the pathogenicity of these viruses does not appear to be different from that of HIV-1. The patient from whom HIV-1<sub>(VAU)</sub> was isolated died of AIDS, like the patient from whom the HIV<sub>MVP5180</sub> group O isolate was obtained.

However, the natural history of infection of the HIV-1<sub>(VAU)</sub> patient is still not clear, but there are several indications that this patient was infected before 1980, as suggested by the death on that date of her second child suffering from a syndrome resembling AIDS.

The invention relates to any variant of the nucleic acid sequences of the HIV-1<sub>(VAU)</sub> virus or of any group O equivalent virus, containing structural proteins which have the same immunological properties as the structural proteins coded for by the env gene comprising the sequence described in Figure 6 and called "vau", also designated by SEQ ID No. 5.

The present invention also relates to compositions containing either antigens according to the invention, or a mixture of antigens according to the invention combined with extracts originating from one or more HIV-1 group O viruses or from other variant viruses, on the one hand, and from one or more HIV-2 and/or HIV-1 viruses, on the other hand, these compositions being optionally labeled. It is possible to use any type of appropriate label: enzymic, fluorescent, radioactive, etc.

#### Nucleic acids

The invention relates to the DNAs or DNA fragments, more particularly cloned DNAs and DNA fragments, obtained from RNA, cDNA or primers which can be used in PCR, or other gene amplification methods, derived from the HIV-1<sub>(VAU)</sub> retrovirus RNA or DNA. The

invention relates more particularly to all the equivalent DNAs, especially to any DNA having sequence homologies with the HIV-1<sub>(VAU)</sub> DNA, in particular with the sequence coding for for the env region of the  
5 HIV-1<sub>(VAU)</sub> strain comprising the sequence corresponding to SEQ ID No. 5 represented in Figure 6 and called "vau". The homology with HIV-1 group M is at least equal to 50%, preferably to 70% and still more advantageously to about 90%. Generally, the invention relates to any  
10 equivalent DNA (or RNA) capable of hybridizing with the DNA or RNA of a group O HIV-1 retrovirus.

The invention also relates to the RNA sequences corresponding to the DNA sequences defined above.

The invention also relates to the HIV-1<sub>(VAU)</sub> virus  
15 integrase gene comprising the sequence identified by the name SEQ ID No. 7 or hybridizing with SEQ ID No. 7. The invention also relates to the RNAs corresponding to the DNA described above.

The subject of the invention is also  
20 compositions containing the peptides or polypeptides encoded by the abovementioned DNA or DNA fragments.

Oligonucleotides derived from the VAU sequence or alternatively from the HIV-1<sub>(VAU)</sub> virus integrase gene, particularly oligonucleotides comprising at least 9  
25 nucleotides, may be used for the detection of group O HIV-1 virus DNA or RNA sequences in biological samples, cell cultures or cell extracts, by the PCR technique or any other gene amplification technique. These sequences could be used either as gene amplification primers or as  
30 probes for the specific detection of the gene amplification products. Also capable of being used as hybridization probes are the amplification products, or their corresponding synthetic sequence, obtained by chemical synthesis (Applied Biosystems).

35 The invention also covers any fragment of at least 100 nucleotides which may be used as a probe in hybridization reactions and capable of permitting

reaction with part of the genome of an HIV-1<sub>(VAU)</sub> variant under high stringency hybridization conditions.

Cloning and sequencing of the HIV-1<sub>(VAU)</sub> env gene

- 5 For the initial PCR amplification of the HIV-1<sub>(VAU)</sub> DNA, the total DNA was extracted from PBMCs infected with HIV-1<sub>(VAU)</sub> and a segment of the pol gene (integrase region) was amplified using degenerate primers:
- 10 primer 4506: 5'AGTGGAT(A/T)(T/C)ATAGAAGCAGAAGT3'; Seq. ID No. 1;  
primer 5011: 5'ACTGC(C/T)CCTTC(A/C/T)CCTTTCCA3'; Seq. ID No. 2;
- 15 The reaction medium including 50 mM KCl, 10 mM Tris-HCl (pH 8.9), 1.5 mM MgCl<sub>2</sub>, 0.1 mg/ml gelatin, 0.2 mM dNTP, 1U of Taq polymerase (Amersham). The PCR was carried out in 43 thermal cycles at 92°C for 10 seconds, 50°C for 1 minute and 72°C for 40 seconds.
- 20 The resulting amplification product was cloned into a pBluescript vector, generating the clone ph4, deposited at the CNCM on 20 October 1994 under No. I-1486, which was subsequently used as a probe to screen a lambda library of low molecular weight DNA, which was digested with EcoRI and was obtained from cells infected
- 25 with HIV-1<sub>(VAU)</sub>. Briefly, the PBMCs infected with HIV-1<sub>(VAU)</sub> were cocultured for 24 hours with new PBMCs stimulated with PHA and depleted of CD8<sup>+</sup> cells, after which a high cytopathic effect (CPE) was visible. The low molecular weight DNA was then extracted according to the Hirt
- 30 method (Hirt 1967), and digested with the enzyme EcoRI. A previous Southern-blot analysis of this DNA had indeed shown that the HIV-1<sub>(VAU)</sub> genome contained only one EcoRI site, permitting the cloning of nonintegrated circular DNA species representing the entire viral genome. The
- 35 resulting digestion product was subjected to agarose gel electrophoresis, and the population of DNA fragments of approximately 8-12 kb in size was purified and ligated

to EcoRI-digested lambda Zap DNA (Stratagene). After encapsidation, plating and screening by hybridization with <sup>32</sup>P-labeled ph4 DNA, a clone, λH34, was identified as being positive, and amplified. The EcoRI insert was  
5 purified, sonicated, and cloned by the "shotgun" technique into the phosphatase-treated vector M13mp18 digested with the enzyme SmaI. One hundred and fifty of the clones obtained were sequenced in a 373A DNA sequencer (Applied Biosystems), and the resulting  
10 sequences were assembled into a single sequence using the Wisconsin GCG DNA analysis package.

Analysis of this sequence revealed numerous nonsense codons in all the reading frames, which is highly suggestive of a hypermutated genome (Vartanian,  
15 et al. 1991). This sequence being unusable, it was consequently decided to amplify, by PCR, the HIV-1<sub>(VAU)</sub> env gene using the total DNA from PBMCs infected with HIV-1<sub>(VAU)</sub>, and the oligonucleotide primers derived from the sequence λH34:

20 primer TH2 5'GCTCTAGATGGGGATCTCCCATGGCAGG3' Seq. ID No. 3;  
primer UH2 5'GCTCTAGATCAGGGAAGAATCCCTGAGTGT3'. Seq. ID No. 4.

The PCR amplification was carried out in  
25 35 thermal cycles at 92°C for 15 seconds, 52°C for 1 minute, 60°C for 2 minutes and 72°C for 2 minutes. The resulting amplification product, of 3.5 kb in size, was cloned into the M13mp18 vector and sequenced by successive reactions, first using the M13 universal  
30 sequencing primer, and then the primers deduced from the upstream sequences. Analysis of the nucleotide and peptide sequences was carried out using the Wisconsin GCG DNA analysis package. The HIV-1<sub>(VAU)</sub> env gene codes for 877 amino acids in total, including the signal  
35 peptide. The nucleotide sequence of the HIV-1<sub>(VAU)</sub> env gene corresponds to Seq. ID No. 5 (see Figure 3).

# Use of nucleic acids as probes

The invention also relates naturally to the use of DNA, cDNA or fragments thereof, or of recombinant plasmids or other equivalent vectors containing these fragments, as probes, for detecting the presence or otherwise of the HIV-1<sub>(VAU)</sub> virus in serum samples or other biological fluids or tissues obtained from patients suspected of being carriers of the HIV-1<sub>(VAU)</sub> virus. These probes are optionally labeled (radioactive, enzymic or fluorescent labels and the like). Probes which are particularly valuable for the implementation of the method for detecting the HIV-1<sub>(VAU)</sub> virus or an HIV-1<sub>(VAU)</sub> variant may be characterized in that they comprise all or a fraction of the DNA complementary to the HIV-1<sub>(VAU)</sub> virus genome or alternatively especially the fragments contained in various clones. An HIV-1<sub>(VAU)</sub> cDNA fraction containing all or part of the env region will be mentioned more particularly.

The probes used in this method for detecting the HIV-1<sub>(VAU)</sub> virus or in diagnostic kits are not in any way limited to the probes described previously. They comprise all the nucleotide sequences obtained from the genome of the HIV-1<sub>(VAU)</sub> virus, an HIV-1<sub>(VAU)</sub> variant or a virus similar by its structure, provided that they allow the detection, using biological fluids from individuals likely to have AIDS, of an HIV-1 group O virus, in particular HIV-1<sub>(VAU)</sub> by hybridization with the HIV-1<sub>(VAU)</sub> virus DNA or RNA.

Particularly advantageous are the probes which, when hybridized with HIV-1, give a strong reaction with HIVs belonging to group O and a weak reaction with HIVs belonging to group M. By way of nonlimiting example, a probe constructed from the HIV-1<sub>(VAU)</sub> virus integrase gene sequence (SEQ ID No. 7) gives, when it is hybridized with HIV-1 under hybridization conditions such as those described in Patent EP 178 978, a strong reaction with group O HIVs and a weak reaction with group M HIVs.

The detection may be performed in any manner known per se, especially:

by bringing these probes into contact either with the nucleic acids obtained from cells contained in biological fluids (for example spinal fluid, saliva and the like), or with these fluids themselves, provided that their nucleic acids have been made accessible to hybridization with these probes, and this under conditions permitting hybridization between these probes and these nucleic acids,

and by detecting the hybridization which may be produced.

The abovementioned diagnosis involving hybridization reactions may also be performed using mixtures of probes derived from HIV-1<sub>(VAU)</sub>, HIV-1 and HIV-2 respectively, provided that it is not necessary to make a distinction between the desired HIV virus types.

The subject of the invention is also expression vectors containing the sequence coding for the HIV-1 envelope proteins or containing the sequence coding for the integrase.

The invention comprises compositions for detecting the presence or otherwise of the HIV-1<sub>VAU</sub> virus in serum samples or samples of other biological fluids or tissues, obtained from patients likely to be carriers of the HIV-1<sub>VAU</sub> virus. These compositions are characterized in that they comprise at least one probe obtained from a nucleotide sequence obtained or derived from the HIV-1<sub>VAU</sub> virus genome, particularly an HIV-1<sub>VAU</sub> DNA fragment containing the region or part of the region coding for for the env protein of the HIV-1<sub>VAU</sub> virus or of an HIV-1<sub>VAU</sub> variant.

Advantageously, the composition described above also comprises a probe obtained from a nucleotide sequence derived from HIV-1 or HIV-2.

Other diagnostic compositions comprise the primers of the invention which are capable of being used

in gene amplification of subgroup O retroviruses or variants of these retroviruses.

**Antigens, especially proteins and glycoproteins**

5

The invention relates to an HIV-1 group (or subgroup) O retroviral protein, or natural or synthetic peptide or polypeptide comprising at least a part of said protein, which is capable of being recognized by  
10 antibodies which may be isolated from serum obtained after an infection with an HIV-1 group O VAU strain, or an HIV-1 group O DUR strain.

The invention relates to an external envelope protein of the HIV-1<sub>VAU</sub> retrovirus encoded by the gene  
15 comprising the sequence corresponding to SEQ ID No. 5. According to a preferred embodiment of the invention, this protein is in addition characterized in that it comprises the amino acid sequence corresponding to Seq ID No. 6 represented in Figure 3 and comprising amino  
20 acid residues 1 to 526. The subject of the invention is also any polypeptide or variant which is derived from said sequence having an epitope which may be recognized by antibodies induced by the HIV-1<sub>VAU</sub> virus.

The abovementioned protein may be obtained in a  
25 glycosylated or nonglycosylated form.

The subject of the invention is also an envelope transmembrane protein comprising the amino acid sequence SEQ ID No. 8 represented in Figure 3 between amino acid residues 527 and 877. This transmembrane protein is,  
30 within the scope of the invention, in glycosylated or nonglycoslated form.

The invention relates to all the antigens, especially proteins, glycoproteins, polypeptides or peptides, obtained by expressing coding sequences of the  
35 HIV-1<sub>(VAU)</sub> genome and having immunological properties equivalent to those of HIV-1<sub>(VAU)</sub>. The antigens are said to be equivalent within the scope of the present

invention provided that they are recognizable by the same antibodies, especially antibodies which can be isolated from serum obtained from a patient who has been infected with an HIV-1<sub>(VAU)</sub>.

5 In particular, the subject of the invention is the peptides or polypeptides which are synthesized chemically and whose amino acid sequence is contained in that of the HIV-1<sub>(VAU)</sub> envelope proteins, which sequence is represented in Figure 3, or the equivalent peptides  
10 or polypeptides.

There should also be included among the equivalent peptides, polypeptides, proteins or glycoproteins, the fragments of the above antigens and the peptides which are prepared by chemical synthesis or  
15 by genetic engineering, so long as they give rise to immunological cross-reactions with the antigens from which they are derived. In other words, the invention relates to any peptide or polypeptide having epitopes which are identical or similar to the epitopes of the  
20 abovementioned antigens and which are capable of being recognized by the same antibodies. Forming part of this latter type of polypeptides are the products of expression of DNA sequences corresponding to DNA sequences coding for for the polypeptides or antigens  
25 mentioned above.

More particularly, the antigens which are obtained from the HIV-1<sub>(VAU)</sub> virus or produced by genetic engineering or conventional chemical synthesis, and which are of the greatest interest within the context of  
30 the present invention, are the antigens which make it possible to obtain a clear distinction between the HIV-1<sub>(VAU)</sub> viruses of the invention and the viruses of the HIV-1 and HIV-2 groups. In this regard, considerable differences have been observed at the level of the HIV-  
35 1<sub>(VAU)</sub> virus envelope protein as well as at the level of the immunodominant epitope of the external portion of the PM protein. It appears that the gag and pol proteins

exhibit greater similarity with the HIV-1 virus than the envelope protein.

The invention also relates to peptides or polypeptides which are identical to the immunodominant region of the HIV-1<sub>(VAU)</sub> envelope transmembrane glycoprotein. This region is represented in Figure 3.

Preferred polypeptides of this region are, for example, those which contain the sequence CKNRLIC or correspond to this sequence. They may also be peptides or polypeptides corresponding to the sequence RLLALETFIQNWWLLNLWGCKNRLIC or comprising this sequence.

Another preferred peptide, identified below by the name "VAU peptide", corresponds to the following sequence or comprises this sequence or any part of this sequence capable of being recognized by antibodies directed against the HIV-1<sub>(VAU)</sub> retrovirus RARLLALETFIQNQQLNLWGCKNRLICYTSVKWNKT.

Variant polypeptides of this sequence are for example the polypeptides represented in Figure 4 for the HIV-1<sub>(MVP5180)</sub> and HIV-1<sub>(ant70)</sub> isolates. These polypeptides may also be derived from the preceding ones by insertion and/or deletion and/or substitution, for example conservative substitution by amino acid residues.

The present invention relates to a peptide obtained from the HIV-1-O DUR virus deposited on 23 February 1995 at the CNCM under the reference I-1542, or a peptide whose sequence is distinguished from that of the above by substitution, deletion or addition of amino acids, this separate peptide nevertheless retaining the antigenic characteristics of the above one.

Other peptides falling within the scope of the invention are defined below.

Thus, a preferred peptide of the invention is a peptide containing at least 4 consecutive amino acids contained in the GAG sequence represented in Figure 8 or in an immunologically similar GAG sequence obtained

from a variant of the HIV-1-O DUR virus, said immunologically similar sequence being recognized by antibodies which also specifically recognize at least one of the sequences AHPQQA, LWTTRAGNP contained in the  
5 GAG sequence of Figure 8.

Preferably, this peptide consists of a peptide whose amino acid sequence is contained either in one of the following sequences:

SPRTLNAWVKAVEEKAFNPEIIPMFALSEGA (1)  
10 MLNAIGGHQGALQVLKEVIN (2)  
GPLPPGQIREPTGSDIAGTTSTQQEQI (3)  
IPVGDIYRKWIVLGLNKMVKMYSVPSILDI (4)  
QGPKEPFRDYVDRFYKTKLAE (5)  
AHPQQA (5a)  
15 LWTTRAGNP (5b)

or in a corresponding immunologically similar sequence, this peptide containing at least 4 consecutive amino acids of one of said sequences.

Preferably also, this peptide consists of a  
20 peptide whose amino acid sequence is contained either in one of the following sequences:

SPRTLNAWVK (6)  
GSDIAGTTST (7)  
QGPKEPFRDYVDRF (8)

25 or in a corresponding immunologically similar sequence, this peptide containing at least four consecutive amino acids of one of said sequences.

Peptides which are particularly preferred in the present invention are the peptides containing:

30 - the amino acid sequence NPEI (9)  
or

- the amino acid sequence AVEEKAFNPEIIPMFM (10), and more particularly peptides whose amino acid sequence is contained, either in one of the following sequences:

35 IGGHQGALQ (23)  
REPTGSDI (24)

or in a corresponding immunologically similar sequence, this peptide containing at least 4 consecutive amino acids of one of said sequences, as well as the peptide whose amino acid sequence is contained, in the following amino acid sequence:

INDEAADWD (25)

or in a corresponding immunologically similar sequence, this peptide containing at least 4 consecutive amino acids of said sequence:

The present invention relates to the nucleic acid sequences coding for peptides (23), (24) and (25) as well as the nucleic acid sequences coding for the immunologically similar sequences, as well as compositions comprising at least one of these nucleic acids.

The invention also relates to the use of at least one of these nucleic acids for detection and discrimination between HIV-1 group M and HIV-1 group O strains.

A peptide derived from the HIV-1-O DUR virus defined above also falls within the scope of the present invention, said peptide containing at least 4 consecutive amino acids of the V3 loop of gp120 represented in Figure 9 or of the corresponding immunologically similar sequence, obtained from a variant of the HIV-1-O DUR virus, said immunologically similar sequence being recognized by antibodies which also specifically recognize at least one of the sequences:

KEIKI (12),  
EREGKGAN (13),  
CVRPGNNSVKEIKI (14),  
QIEREGKGANSR (15).

This peptide preferably contains:  
a) either the sequence

CVRPGNNSVKEIKIGPMAWYSMQIEREGKGANSRTAFC (11) or a part of this sequence which contains at least 4 amino acids

b) or an amino acid sequence which is separate from the sequence of a) in which one or more amino acids are replaced with one or more amino acids, with the proviso that the peptide retains its reactivity with an antiserum against the abovementioned peptide,

c) or an amino acid sequence which is separate from a) or b), in which one or more amino acids have been deleted or added, with the proviso that the peptide retains its reactivity with an antiserum against the peptide of a),

d) or a corresponding immunologically similar sequence or part of sequence.

Preferably also, this peptide contains either the sequence KEIKI (12),

or

the sequence EREGKGAN (13),

or

the sequence GPMWYSM (16).

In a particularly preferred manner, a peptide as defined above contains the amino acid sequence CVRPGNNSVKEIKI (14) or the sequence QIEREGKGANSR (15).

A peptide derived from the HIV-1-O DUR virus as defined above also falls within the scope of the invention, said peptide containing at least 4 consecutive amino acids, whose entire sequence is contained in the sequence of the immunodominant region of gp41 represented in Figure 9 or in a corresponding immunologically similar sequence, obtained from a variant of the HIV-1-O DUR virus, said immunologically similar sequence being recognized by antibodies which also specifically recognize at least one of the following sequences:

RLLALETLMQNQQL (17),

LNLWGCRGKAICYTSVQWNETWG (18),  
CRGKAI (19),  
SVQWN (20),  
RLLAETLMQNQQLLNLWGCRGKAICYTS (21),  
5 QNQQLLNLWGCRGKAICYTSVQWN (22).

This peptide is preferably a peptide containing  
the sequence RLLAETLMQNQQL (17), or  
LNLWGCRGKAICYTSVQWNETWG (18) or part of this peptide  
10 (18) containing:

a) either the sequence CRGKAI (19) or the  
sequence SVQWN (20) in which Q is, where appropriate,  
replaced by a different amino acid, which is  
nevertheless also different from K, or the two  
15 sequences at the same time,

b) or an amino acid sequence which is separate  
from the sequence of a) in which one or more amino  
acids are replaced with two amino acids, with the  
proviso that the peptide retains its reactivity with an  
20 antiserum against the peptide of a),

c) or an amino acid sequence which is separate  
from a) or b), in which one or more amino acids have  
been deleted or added, with the proviso that the  
peptide retains its reactivity with an antiserum  
25 against the peptide of a),

d) or in a corresponding immunologically  
similar sequence or part of sequence.

Preferably also, this peptide possesses one or  
30 the other of the following characteristics:

- its N-terminal sequence which contains at  
least 8 amino acids is not immunologically recognized  
by antibodies formed against the sequence RILAVERY  
contained in the immunodominant region of gp41 of the  
35 HIV-1-LAI strain.

- it is not recognized by antibodies formed  
against the peptide SGKLIC of the HIV-1-LAI strain.

- it contains either of the following two sequences:

RLLALETMONQQLLNWGCGRGKAICYTS (21)

QNQQLLNWGCGRGKAICYTSVQWN (22)

5

#### Synthesis of VAU peptides

A VAU peptide was prepared by the conventional solid phase peptide synthesis technique using the "continuous flow" Fmoc method. The peptide was prepared using a Milligen 9050 PEP synthesizer and using the "Millipore" PEG PAL resin, substituted with the first C-terminal amino acid residue. The side chains of the amino acids are protected by the following groups: Pmc for arginine; Trt for asparagine, glutamine and cysteine; Boc for lysine; tBu ester for glutamic acid; tBu ether for serine, threonine and tyrosine. The temporary Fmoc groups are removed with a 20% piperidine solution in DMF. The reactions for coupling each amino acid are performed with 6 equivalents of DIPCDI and HOBT. Some residues require a double coupling especially arginines 1 and 23, cysteines 19 and 26, asparagine 11, glutamines 10, 12 and 13, alanine 4, isoleucine 9 and leucines 2, 3, 14 and 15.

After coupling, the resin is dried under vacuum. The peptide is cleaved from the support by the K reagent for 4 hours at room temperature. The crude peptide is precipitated and washed with ethyl ether. The product is purified by high-pressure liquid chromatography (HPLC) in a WATERS LC PREP 4000 instrument with WATERS Delta Pak C18 40 x 100 mm cartridges, flow rate 30 ml/min, acetonitrile/0.1% TFA gradient. The fractions containing the peptide are combined, concentrated in a rotary evaporator and then lyophilized.

#### 35 Cyclization

The peptide (0.025 mM) is dissolved in a 10 mM ammonium acetate solution. The pH is adjusted to 8.5

with 1M ammonium hydroxide solution. The pH is readjusted after 3 or 4 hours. The cyclization is monitored by HPLC at 214 nm and 280 nm, WATERS Delta Pak C18 5µ column, acetonitrile/0.1% TFA gradient. The cyclization is complete after 15 hours. The pH is brought to 6 using 97-100% acetic acid, the solution is lyophilized and then purified under the same conditions as for the crude peptide.

The peptide is checked by HPLC and by mass spectrometry according to the electrospray technique (FISON VG Trio 2000 spectrophotometer).

Fmoc: 9-Fluoroenylmethyloxycarbonyl

Pmc: 8-Methylpentane-6-sulfonylchroman

Trt: Tritryl

Boc: Tertbutyloxycarbonyl

tBU: tert butyl

DIPCDI: Diisopropylcarbodiimide

HOBT: 1-Hydroxybenzotriazole

TFA: Trifluoroacetic acid

Reagent K: Phenol/water/thioanisole/ethanedithiol/TFA;  
2.5 ml/2.5 ml/2.5 ml/1.5 ml/41 ml

Comparison of the amino acid sequence of the HIV-1<sub>(VAU)</sub> envelope with the corresponding sequence of other HIV viruses.

Western-blot analysis of a series of serum samples obtained from a patient infected with HIV-1<sub>(VAU)</sub> is presented in Figure 2. Nitrocellulose strips, carrying proteins separated by electrophoresis and obtained from purified HIV particles (LAV BLOT, SANOFI DIAGNOSTICS PASTEUR), were incubated with serum samples and their reactivity was evaluated according to the procedures recommended by the manufacturer. The results obtained are the following: strip 1: proteins specific for HIV-2, which have been reacted with a serum sample obtained in February 1992 from the HIV-1<sub>(VAU)</sub> patient. Strips 2-7: HIV-1 positive sera; sera from the HIV-1<sub>(VAU)</sub>

patient: 2: obtained in November 1990; 3: in December  
1990; 4: in February 1991; 5: in February 1992; 6:  
negative control; 7: positive control (serum from an  
individual infected with HIV-1). The names and the size  
5 of the proteins (in kD) are indicated in the margin.

Figure 3 shows an alignment of the amino acid  
sequence of the HIV-1<sub>(VAU)</sub> envelope with the corresponding  
sequence of the HIV-1-LAI reference isolate (Wain-  
Hobson, et al. 1985). The signal peptides, the V3 loop  
10 and the gp41 immunodominant epitope are highlighted by  
shaded rectangles. The site of cleavage between the  
external envelope glycoprotein gp120 and the  
transmembrane gp41 is indicated by arrows. The vertical  
lines between the amino acid letters indicate complete  
15 identity, colons (:) indicate high homology, and dots  
(.) indicate limited homology between individual amino  
acids. The alignment was performed using the GAP program  
of the Wisconsin GCG package.

The original version (1.0) of the GAP and  
20 BESTFIT programs was written by Paul Haeberli from a  
detailed study of the publications of Needleman and  
Vunsch (J. Mol. biol. 48, 443-453 (1970) and of Smith  
and Waterman (Adv. Appl. Math. 2; 482-489 (1981). The  
limited alignments were developed by Paul Haeberli and  
25 added to the package to constitute the 3.0 version. They  
were then fused into a single program by Philip Marquess  
to constitute the 4.0 version. The gap absence penalties  
in the alignment of the proteins were modified as  
suggested by Rechid, Vingron and Argos (CABIOS 5; 107-  
30 113 (1989)).

The alignment of Figure 3 shows numerous regions  
of high divergence, with a few domains retained here and  
there. These retained regions correspond roughly to the  
domains also retained in the conventional HIV-1 isolates  
35 (Alizon et al. 1986, Benn et al. 1985). Among the  
divergent domains, the V3 loop, also called principal  
determinant of neutralization (Javaherian et al. 1990,

Javaherian et al. 1989, Matsushita et al. 1988) is clearly one of the most divergent, although the two cysteines defining the loop are retained. The sequence of the cap of the loop, GPGRAPH for HIV-1-LAI is GPMAWY in HIV-1<sub>(VAU)</sub>. This unit of the cap is identical to that of the Cameroonian group O isolate HIV<sub>(ANT70)</sub> (Van den Heasevelde et al. 1994), but is different from that of the other group O isolate, HIV<sub>MVP5180</sub> (Gürtler et al. 1994), for which the motif is GPMRWR.

10 In the entire envelope, 29 potential N-glycosylation sites were identified in total, of which 13 are retained compared with other HIV-1 envelope proteins. 19 retained cysteines were also found in total, which indicates that the overall folding  
15 architecture of the protein is retained, but 5 nonretained cysteines were found.

Figure 4 shows the multiple alignment of the immunodominant peptides in the extracellular segment of the transmembrane envelope glycoprotein of various HIV-1  
20 isolates. All the sequences are compared to the HIV-1-LAI reference sequence. Hyphens indicate identity with HIV-1-LAI. The alignment was made with the aid of the PILEUP program of the Wisconsin GCG package.

In the PILEVP program, the assembling strategy  
25 represented by the dendrogram is called UPGMA, which means "unweighted pair-group method using arithmetic averages" (Smith, P.H.A. Sokal, R.R. (1973) in Numerical Taxonomy (pp. 230-234), W.H. Freeman and Company, San Francisco, California, USA). Each pair alignment in  
30 PILEVP uses the Needleman and Wunsch method (Journal of Molecular Biology 48; 443-453 (1970)).

As shown in Figure 4, the amino acid sequence of the immunodominant epitope of the external portion of the TM protein (Gnann et al., 1987) is substantially  
35 different from that of other HIV-1 and HIV-2 isolates. However, it retained most of the amino acids which were

found to be conserved between the HIV-1 and HIV-2 viruses.

It was found that some specific amino acids were conserved only between group O viruses: such is the case for lysine in position 21 in a peptide of 26 amino acids, for threonine in position 7 and asparagine in position 11. These differences could explain the absence of detection of conventional HIV-1 envelope antigens by one of the sera from the HIV-1<sub>(VAU)</sub> patient and also probably by that of the patients infected by other group O viruses. Overall, the comparison between the HIV-1-LAI and HIV-1<sub>(VAU)</sub> envelope sequences showed a 50% identity. The HIV-1<sub>(VAU)</sub> envelope sequence was also compared to that of other HIV representatives including the two members of HIV-1 group O described and sequenced: HIV-1<sub>ANT70</sub> and HIV-1<sub>MVP5180</sub> and SIV representatives. The results of this analysis, which are presented in Table 1, establish that HIV-1<sub>(VAU)</sub> belongs to group O. The HIV-1<sub>(VAU)</sub> envelope is 70% identical to the HIV-1<sub>ANT70</sub> envelope and 71% identical to HIV-1<sub>MVP5180</sub>. Among the most common HIV-1 subtypes, the identity at the level of the envelope is comparable, ranging from 74% to 80%.

The relationship between HIV-1<sub>(VAU)</sub>, other members of the phylogeny of HIV-1 viruses and the two viruses of group O recently described was analyzed by constructing a phylogenetic tree of unweighted parsimony using the nucleotide sequence of the env transmembrane region. The result of this analysis is represented in Figure 5 in which the numbers indicate the number of nucleotide changes. Figure 5 shows that HIV-1<sub>(VAU)</sub> is roughly equidistant from the other two group O viruses and that, overall, these three viruses appear to be approximately equidistant from each other. Indeed, the number of nucleotide changes between HIV-1<sub>MVP5180</sub> and HIV-1<sub>(VAU)</sub> is 218 in the segment of the genome analyzed, whereas the distance is 183 between HIV-1<sub>MVP5180</sub> and HIV-1<sub>ANT70</sub>, and 213 between HIV-1<sub>ANT70</sub> and HIV-1<sub>(VAU)</sub>. This divergence profile is very similar to that which exists in all the other HIV-1 subtypes, where the number of single nucleotide changes which exist between two different subtypes ranges from 157 (subtype E to subtype F) to 219 (subtype A to subtype D).

Table 1 shows the comparison of the envelope sequences of different viruses related to HIV-1. The numbers indicate the percentage of amino acid identity between the envelope sequences, as calculated using the GAP program of the Wisconsin GCG package. In the case of HIV<sub>ANT70</sub>, only the external envelope protein was used in the comparison.

#### Compositions comprising HIV-1<sub>(VAU)</sub> antigens

Generally, the invention relates to any composition which can be used for the in vitro detection of the presence, in a biological fluid, especially from individuals who have been brought into contact with HIV-1<sub>(VAU)</sub>, or with antibodies against at least one of the HIV-1<sub>(VAU)</sub> antigens. This composition can be applied to the selective diagnosis of infection by an HIV-1 group O by using diagnostic techniques such as those described

in Patent Applications EP 84401,834 and EP 87400,151,4.  
Within the context of the present invention, any  
constituent comprising antigenic determinants capable of  
being recognized by antibodies produced against HIV-1<sub>(VAU)</sub>  
5 is used, for example recombinant antigens or peptides or  
chemically synthesized peptides defined from the  
sequence of the HIV-1<sub>(VAU)</sub> envelope. In this regard, the  
invention relates more particularly to compositions  
containing at least one of the HIV-1<sub>(VAU)</sub> virus envelope  
10 proteins. There may be mentioned, by way of examples of  
compositions, those which contain proteins,  
glycoproteins or peptides from the envelope protein  
corresponding to the entire 590-620 region of the HIV-  
1<sub>(VAU)</sub> gp41 protein or to the parts of this region which  
15 are specific for HIV-1<sub>(VAU)</sub> such as the peptides  
-TFIQN- or -WGCKNR-.

The invention also relates to compositions  
combining recombinant or synthetic HIV-1<sub>(VAU)</sub> proteins  
and/or glycoproteins and/or peptides with proteins  
20 and/or glycoproteins and/or peptides from HIV-1 and/or  
HIV-2 and/or from another HIV-1 group O which are  
obtained by extraction or in lysates or by recombination  
or by chemical synthesis and/or peptides which are  
derived from these proteins or glycoproteins and which  
25 are capable of being recognized by antibodies induced by  
the HIV-1 and/or HIV-2 and/or HIV-1 group O virus.

The diagnostic compositions containing antigenic  
determinants capable of being recognized by antibodies  
directed against HIV-1<sub>(VAU)</sub>, in particular the peptide  
30 compositions, may be included in or combined with  
compositions or kits already available for detecting  
infection by HIV-1 and/or HIV-2 retroviruses, so as to  
extend the detection range of the kits to the detection  
of HIV-1 group O retroviruses.

35

By way of nonlimiting examples:

- either core proteins, particularly the gag, pol, HIV-1 and HIV-2 proteins or peptides thereof, and HIV-1<sub>(VAU)</sub> envelope proteins or peptides,

5       - or HIV-1 envelope glycoproteins, HIV-2 envelope glycoproteins and HIV-1<sub>(VAU)</sub> envelope glycoproteins,

10       - or mixtures of HIV-1 proteins and/or glycoproteins, HIV-2 proteins and/or glycoproteins and HIV-1<sub>(VAU)</sub> envelope proteins and/or glycoproteins.

15       It is important to note that, although the antibodies from patients infected with HIV-1 group O viruses react strongly with gag and pol antigens from HIV-1 group M viruses, their reactivity is practically zero with group M virus envelope antigens. It is therefore important that the composition of the present invention comprise at least one protein or one peptide of the HIV-1<sub>(VAU)</sub> envelope so that this virus can be detected with certainty.

20       Such compositions, when used in diagnosis, consequently help the diagnosis of AIDS or of the symptoms associated with it, which extend over a broader spectrum of causative etiological agents. It goes without saying that the use of diagnostic compositions which contain only HIV-1<sub>(VAU)</sub> envelope proteins and/or glycoproteins is nonetheless useful for the more selective detection of the category of retrovirus which may be held responsible for the disease.

30       Methods and kits for the diagnosis of infections caused especially by the HIV-1<sub>(VAU)</sub> virus

35       The present invention relates to a method for the in vitro diagnosis of infection caused by HIV viruses, etiological agents of AIDS and related syndromes, which comprises bringing a serum or another biological medium, obtained from a patient or subject being subjected to the diagnosis, into contact with a

composition containing at least one protein, glycoprotein or peptide from HIV-1<sub>(VAU)</sub>, and detecting a possible immunological reaction. Examples of such compositions were described above.

5 Preferred methods involve, for example, immunofluorescence or ELISA type immunoenzymic reactions. The detections may be effected by direct or indirect immunofluorescence measurements or direct or indirect immunoenzymic assays.

10 Such detections comprise for example:

- depositing defined quantities of the extract or of the desired antigenic compositions in accordance with the present invention into the wells of a microplate;

15 - introducing into each well a serum, diluted or undiluted, which is capable of containing the antibodies, the presence of which has to be detected in vitro;

- incubating the microplate;

20 - carefully washing the microplate with an appropriate buffer;

- introducing into the wells of the microplate specific labeled antibodies to human immunoglobulin, the labeling being performed with an enzyme chosen from those which are capable of hydrolyzing a substrate such that the latter then undergoes modification of its absorption of radiation, at least in a defined wavelength band, and

25 - detecting, preferably in a comparative manner relative to a control, the extent of the hydrolysis of the substrate as a measure of the potential risks or of the actual presence of the infection.

30 The present invention also relates to kits or boxes for the diagnosis of HIV-1<sub>(VAU)</sub> virus infection, which comprise in particular:

- an extract, a more purified fraction, or a synthetic antigen derived from the types of viruses indicated above, this extract fraction or antigen being labeled, for example, radioactively, enzymically, 5 fluorescently or otherwise,

- antibodies to human immunoglobulins or a protein A (which is advantageously attached to a support which is insoluble in water) such as agarose beads for example) or microplate wells, and the like),

10 - optionally, a sample of biological fluid or cells obtained from a negative control subject;

- buffers and, where appropriate, substrates for visualizing the label.

The subject of the invention is also immunogenic 15 compositions which are capable of inducing the formation of antibodies recognizing antigens which can be obtained by chemical synthesis or by recombination.

#### Serology

20 The capacity of the serum antibodies from the patient infected with HIV-1<sub>(VAD)</sub> to react with HIV-1 antigenic preparations was evaluated using various commercially available kits: Sanofi Diagnostics Pasteur, (Genelavia Mixt) Abbott, Wellcome, and Behring. The 25 reactivity of these antibodies with various HIV-1 proteins was examined using the Sanofi Diagnostics Pasteur Western-blot kit, following the procedures recommended by the manufacturer.

More precisely, the patient's serum was examined 30 several times using HIV-1 specific ELISA kits. It was first tested and proved to be positive in 1990, being noted 7.33 (this figure corresponds to the ratio of the measured OD to the background OD) with the Sanofi Diagnostics Pasteur kit, 3.50 with the Abbott kit and 35 2.70 with the Wellcome kit. During the use of reagents specific both for HIV-1 and HIV-2, the serum was noted

1.42 with the Behring kit and 4.40 with the Wellcome kit.

The capacity of the patient's serum to react on different dates with different HIV-1 structural proteins was studied using the HIV-1 LAV BLOT immunoblot assay, a test marketed by Sanofi Diagnostics Pasteur. As shown in Figure 5 with all the serum samples tested, only a very weak reactivity of the serum with the HIV-1 env proteins gp160 and gp120 was noted. However, the serum reacted strongly with the HIV-1 gag proteins p55 (gag precursor) and p24 (CA), and with the pol products p66 (RT) and p34 (IN). By HIV-2 immunoblotting, only a very weak reactivity was detected with the gag p26.

This illustrates that the detection of antibodies specific for group O with commercially available serum diagnostic kits should be carefully controlled. Although serum antibodies from patients infected with group O viruses show strong cross-reactions with the group M gag and pol antigens, they show few or no reactions with the group M envelope antigens. Consequently, it is possible to assume that a significant proportion of these patients might not be detected using some kits based on group M envelope antigenic reagents. Indeed, in a recent preliminary study of several sera from patients infected with group O, it was found that the capacity to detect antibodies specific for group O was very different depending on the detection kit used (Loussert-Ajaka, I., Ly, T.D., Chaix, M.L., Ingrand, D., Saragosti, S., Courroucé, A.M., Brun-Vézinet, F. and Simon, F. (1994). HIV-1/HIV-2 seronegativity in HIV-1 subtype O infected patients. *Lancet*. 343, 1393-1394.). This implies that a careful and extensive study of the reactivity of a large number of group O sera with all the diagnostic kits available on the market is necessary.

Compositions comprising polyclonal or monoclonal antibodies prepared from recombinant or synthetic antigens from the HIV-1<sub>(VAU)</sub> virus.

5 The invention relates to a serum capable of being produced in animals by inoculating them with HIV-1<sub>(VAU)</sub>, particularly the antigenic epitopes of HIV-1<sub>(VAU)</sub> and more particularly the antigenic epitopes of the HIV-1<sub>(VAU)</sub> virus envelope protein. The invention relates more particularly to the polyclonal antibodies  
10 more specifically oriented against each of the antigens, especially proteins or glycoproteins of the virus. It also relates to monoclonal antibodies produced by various techniques, these monoclonal antibodies being respectively oriented more specifically against the  
15 various HIV-1<sub>(VAU)</sub> proteins, particularly the HIV-1<sub>(VAU)</sub> envelope proteins.

These polyclonal or monoclonal antibodies can be used in various applications. There may be mentioned essentially their use for neutralizing the corresponding  
20 proteins, or even for inhibiting the infectivity of the whole virus. They may also be used for example to detect viral antigens in biological preparations or to carry out procedures for purifying the corresponding proteins and/or glycoproteins, for example during their use in  
25 affinity chromatography columns.

By way of example, anti-envelope antibodies or anti-gag antibodies are reagents which can be used in diagnosis, in particular for the detection of HIV-1 group O particles by antigen capture ELISA.

30 The invention relates to antibodies directed against one or more HIV-1<sub>(VAU)</sub> viral antigens produced from amino acid sequences of HIV-1<sub>(VAU)</sub>. Techniques for obtaining antibodies from antigenic epitopes similar to the antigenic epitopes of the HIV-1<sub>(VAU)</sub> virus of the  
35 present invention have been described previously.

The technique for the preparation of antibodies which is described in the publication by Ulmer et al., 1993, may be used by persons skilled in the art to prepare the antibodies of the present invention, the  
5 modifications which make it possible to adapt this technique to the antigens of the present invention forming part of the knowledge of persons skilled in the art.

10 Study of the immunoreactivity of the vau peptide

The immunoreactivity of the vau peptide was confirmed, after experimental ELISA plates had been prepared, according to a procedure established for a screening test for anti-HIV antibodies. This test is  
15 based on the detection of a solid phase prepared with the peptide which mimics the immunodominant epitope of the envelope glycoprotein of the HIV-1 group (or subgroup) O virus, VAU isolate. The implementation of the test was modeled on the procedure proposed by the  
20 Genelavia® Mixt kit, using the reagents in that kit.

The experimental data collated in the two tables of Figures 21 and 22 show that:

a) the four sera taken from patients contaminated with the HIV-1 group (or subgroup) O virus  
25 are very reactive with the vau peptide;

b) the ten sera supposedly taken from patients contaminated with the HIV-1 (group or subgroup) O virus, among the 19 sera sent out by the Pasteur Institute of Yacoundé, are also highly reactive  
30 with this same peptide;

c) the sera (4 samples) taken from individuals contaminated with the HIV-1 subtype B virus (in the acute phase) are not reactive with the vau peptide;

d) the sera taken from asymptomatic blood donors (48 samples tested) are not reactive with the vau peptide; These experimental data, although limited (in view of the paucity of HIV-1 group (or subgroup 5 O) antibody-positive samples), bear witness to the sensitivity and specificity of the peptide selected.

From the above text, it follows that the invention also relates to the detection of the HIV-1<sub>(vau)</sub> virus or of a variant by virtue of the use of the 10 antibodies described above in a method involving various stages, these stages being specifically intended to reveal the characteristic properties of the HIV-1<sub>(vau)</sub> virus.

The invention also relates to the detection of 15 the HIV-1<sub>(vau)</sub> virus by molecular hybridization.

Generally, this method for detecting the HIV-1<sub>(vau)</sub> virus or a variant in serum samples or samples of other biological fluids or tissues, obtained from patients liable to be carriers of the HIV-1<sub>(vau)</sub> virus, 20 comprises the following stages:

- the manufacture of at least one optionally labeled probe;

- at least one hybridization stage performed under conditions permitting hybridization by bringing 25 the nucleic acid of the suspect patient's sample into contact with said labeled probe and optionally immobilizing the complex formed on an appropriate solid support,

- where appropriate, washing said solid support 30 with a suitable washing solution,

- the detection of said complex and therefore of the presence or otherwise of the HIV-1<sub>(vau)</sub> virus by an appropriate detection method known to those skilled in the art.

35

In another preferred embodiment of the method according to the invention, the abovementioned hybridization is performed under nonstringent conditions and the membrane is washed under conditions adapted to those for the hybridization.

By using serology or a gene amplification technique such as specific Polymerase Chain Reaction (PCR), the extent of the HIV-1 group O epidemic was precisely evaluated. It was found that 5 to 10% of patients infected with HIV-1 in Cameroon are in fact infected with group O viruses. However, apart from the virus isolate described here, the propagation of the group O virus outside West Central Africa has not been documented. The patient from whom HIV-1<sub>(VAU)</sub> was isolated has always lived in France and has never traveled to Africa. Up until now, we have no precise proof relating to the origin of her infection, but this case indicates that a degree of propagation of the group O viruses in Europe has already occurred.

The invention also relates to a process of detection and discrimination, in a biological sample, between antibodies characteristic of an HIV-1 group (or subgroup) O retrovirus and antibodies characteristic of a retrovirus of the HIV-1-M type, characterized by placing this biological sample in contact with a peptide which does not react with the antibodies characteristic of a retrovirus of the HIV-1-M type, in particular one chosen from the peptides (1), (2), (3), (4), (5a), (5b), (9) and (10) described above.

Also, the invention relates to a process of detection and discrimination, in a biological sample, between antibodies characteristic of an HIV-1 group (or subgroup) O retrovirus and antibodies characteristic of a retrovirus of the HIV-1-M type, characterized by placing this biological sample in contact with the peptide derived from one of the HIV-1 M viruses taken into consideration in Figures 8 and 9 and homologous to

a peptide chosen from the peptides (1), (2), (3), (4), (5a), (5b), (9) and (10), the sequence of this homologous peptide resulting from vertical alignments of its own successive amino acids which are themselves contained in the pertinent peptide sequence relative to the corresponding HIV-1-M virus and represented in Figure 8 or 9 with the successive amino acids of the sequence of the peptide chosen, as also follows from Figure 8 or 9.

10 According to the present invention, the process of detection and discrimination between infection by an HIV-1 group (or subgroup) O retrovirus and an HIV-1 subgroup M retrovirus is characterized by placing serum, obtained from individuals subjected to an AIDS  
15 diagnostic test, in contact, in particular, with the peptide RILAVERY.

In addition, the process for detection of infection due either to an HIV-1 subgroup O or HIV-1 subgroup M retrovirus is characterized by the use of  
20 mixtures of two categories of peptides, those of the first category corresponding to the peptides (1), (2), (3), (4), (5a), (5b), (9) and (10).

Moreover, the process for discrimination between an infection due to an HIV-1-O DUR retrovirus and an infection due to another type of HIV-1-O retrovirus, is characterized by placing the biological  
25 test sample in contact with any of the peptides (11) to (15) or of the peptides (17) to (20).

Alternatively, it is a process for  
30 discrimination between an infection by an HIV-1 group (or subgroup) O retrovirus and an HIV-1 subgroup M retrovirus, using a serine protease whose cleaving action is carried out on an SR dipeptide, and comprising the detection of a cleavage or of a non-  
35 cleavage of the V3 loop of gp120 of the retrovirus, depending on whether this retrovirus is an HIV-1 group

(or subgroup) O retrovirus or an HIV-1 subgroup M retrovirus.

The invention also relates to a composition for detection and discrimination, in a biological sample, between an HIV-1 subgroup M retrovirus and an HIV-1 group (or subgroup) O retrovirus, comprising a mixture of two categories of peptides, the first being in particular those identified (1), (2), (3), (4), (5a), (5b), (9) and (10).

Monoclonal antibodies specific for the sequences of each of the peptides (1) to (20) also fall within the scope of the present invention.

The invention also relates to a plasmid chosen from those which were deposited at the CNCM on 24 February 1995 under the references I-1548, I-1549 and I-1550.

The invention is also directed towards nucleic acids containing a sequence which codes for each of the peptides (1) to (20) defined in the present invention.

Among the preferred nucleic acid sequences, the nucleotide sequences represented in Figures 10, 11 or 12 will be chosen.

The invention also relates to vectors containing a nucleic acid as defined above.

The invention is also directed towards cells liable to contain any one of said nucleic acids or of said vectors.

The present invention also relates to a virus such as that deposited on 23 February 1995 at the CNCM under the reference I-1542.

A virus also falling within the scope of the invention is a virus of the same group as the above, characterized in that consensus peptides of this virus are recognized by antibodies which specifically recognize a polypeptide or a peptide defined above.

The genomic RNA of this virus also falls within the scope of the invention.

Also falling within the scope of the invention is a box or kit for detection of antibodies in the serum or any other biological sample from a patient  
5 liable to be infected with a human retrovirus of the HIV type, characterized in that it comprises:

- at least one polypeptide or one peptide having, in particular, as its sequence one of the  
10 sequences (1) to (20) described above.

- means allowing the reaction for formation of the immunological complex between the polypeptide(s) or the peptide(s) and the antibodies which may be present in the biological sample to be tested, for example one  
15 or more incubation buffers, if needed,

- a negative control sample,  
- means for visualizing the antigen/antibody complex formed.

Also according to the invention, this kit  
20 contains, in addition, at least one consensus peptide or polypeptide derived from another HIV strain or from a peptide or polypeptide comprising

either an amino acid sequence which is separate from the sequence of this polypeptide or peptide, in which one or more amino acids are replaced with other amino acids, with the proviso that the peptide or polypeptide retains its reactivity with an antiserum  
25 against the consensus peptide or polypeptide,

or an amino acid sequence in which one or more  
30 amino acids have been deleted or added, with the proviso that the peptide or polypeptide retains its reactivity with an antiserum against the consensus peptide or polypeptide.

Preferably, a kit according to the invention  
35 will contain, in addition, at least one peptide or polypeptide derived from another HIV strain, preferably the HIV-LAI strain.

The invention also relates to a polypeptide composition for the in vitro diagnosis of an infection due to a retrovirus according to the invention, or to one of its variants, this diagnosis being made on a biological sample liable to contain antibodies formed after said infection. This composition is characterized in that it comprises at least one of the peptides (1) to (20).

The biological sample may consist in particular of blood, plasma, serum or any other biological extract. The above compositions may be used for the detection of antibodies in one of the abovementioned biological samples.

The invention is therefore also directed toward a method for the in vitro diagnosis of an infection due specifically to a retrovirus of the HIV type, characterized by the steps of:

- placing a biological sample, which is liable to contain antibodies produced after an infection by an HIV-1 group (or subgroup) O retrovirus, in contact with a peptide as defined above, or with a peptide composition as defined above, under suitable conditions which allow the formation of an immunological complex of the antigen/antibody type,

- detection of the possible presence of the complex.

The invention moreover relates to an immunogenic composition, characterized in that it comprises at least one peptide in combination with a pharmaceutical vehicle which is acceptable for making up vaccines.

The invention also relates to a process for the preparation of capsid proteins and gp41 and gp120 glycoproteins of a retroviral strain according to the invention, the process being characterized by the following steps:

- lysis of the cells infected with an HIV-1 retrovirus according to the invention and separation of the supernatant and of the infected cells or lysis of the viral pellets prepared by centrifugation,

5           - deposition of the cell extract and/or of the viral extract on an immunoadsorbant containing purified antibodies, which are obtained from the serum of an individual infected by a retrovirus according to the invention and advantageously attached to a suitable  
10 support, said serum of the infected individual having the capacity to react strongly with envelope proteins of the virus according to the invention,

15           - incubation in the presence of a buffer and for a sufficiently long period to obtain the formation of an antigen/antibody immunological complex,

          - washing of the immunoadsorbant with a buffer in order to remove the molecules not retained on the support,

          - recovery of the desired antigenic proteins.

20           According to a first embodiment of this preparation process, the separation and the recovery of the capsid proteins and of the gp41 and gp120 glycoproteins of HIV-1 DUR are carried out by electrophoresis and by electroreduction of the  
25 proteins.

          According to another embodiment of this preparation process, the proteins are recovered by:

          - elution of the proteins attached to the above immunoadsorbant,

30           - purification of the products thus eluted on a chromatography column containing, attached to the separation support, antibodies which recognize the capsid proteins and the gp41 and gp120 glycoproteins of HIV-1 group (or subgroup) O DUR.

Also falling within the scope of the invention is a process for the production of a peptide or polypeptide according to the invention, this peptide or polypeptide being obtained

5       - either by expression of a nucleic acid of the invention,

          - or by chemical synthesis, by addition of amino acids until this peptide or this polypeptide is obtained.

10       The standard principles and processes of genetic engineering may be used here ("Molecular cloning", Sambrook, Fritsch, Maniatis, CSH 1989).

Also falling within the scope of the invention is a process for the production of a nucleic acid  
15       defined above, which may be produced either by isolation from a virus of the invention, or by chemical synthesis, or by using techniques of in vitro amplification of nucleic acids from specific primers.

Oligonucleotide primers also according to the  
20       invention have a sequence consisting of at least eight consecutive nucleotides of the following nucleotide sequences:

ATT CCA ATA CAC TAT TGT GCT CCA-3'  
AAA GAA TTC TCC ATG ACT GTT AAA-3'  
25       GGT ATA GTG CAA CAG CAG GAC AAC-3'  
AGA GGC CCA TTC ATC TAA CTC-3'

These primers may be used in a gene amplification process, for example by PCR or an equivalent technique, of a nucleotide sequence coding  
30       for a peptide of the invention. Tests carried out with these primers gave conclusive results.

Also, the invention relates to a kit allowing amplification by PCR or an equivalent technique described above.

35       Also falling within the scope of the present invention is a process for detection of the presence, in a biological sample, of nucleic acid(s)

characteristic of an HIV-1 group (or subgroup) O DUR  
retrovirus, including a retrovirus according to the  
invention. This process comprises a placing in contact  
of a cDNA formed from RNA(s) contained in this  
5 biological sample, under conditions allowing the  
hybridization of this cDNA with the retroviral genome,  
and the execution of a gene amplification on this viral  
sample.

The invention also relates to a viral lysate as  
10 obtained by lysis of cells infected with a virus  
according to the invention.

A protein extract from an HIV-1<sub>(DUR)</sub> (or  
HIV-1<sub>(VAU)</sub>) strain containing in particular a peptide or  
a polypeptide as defined above also falls within the  
15 scope of the invention.

The invention relates to specific peptides  
obtained from the structure of HIV-1 group (or  
subgroup) O DUR or from variants of this retrovirus and  
which make it possible

20 either to discriminate, depending on the case,  
- globally between HIVs-1 belonging to the  
category O and HIVs-1 belonging to the category M,  
- or, more specifically, between viruses  
belonging to the subgroup characteristic of the HIV-1  
25 group (or subgroup) O DUR and other viruses of the  
subgroup O,

or, on the other hand, to recognize most, if  
not all, of the retroviruses both of the group (or  
subgroup) O and of the subgroup M.

30 Also falling within the scope of the invention  
are the corresponding peptides obtained from  
corresponding structural proteins of other HIV-1 group  
(or subgroup) O or HIV-1 subgroup M viruses, in  
particular those derived from the GAG, gp120 and gp41  
35 structural proteins whose parts are indicated in the  
diagrams, these homologous peptides ensuing from their  
being placed in alignment, as also results from the

diagrams with the peptides obtained from the HIV-1 group (or subgroup) O DUR, more particularly identified in the present text.

5 Similarly, certain homologous peptides may be used in those tests which make it possible to carry out the abovementioned discriminations, it being understood in this case that they are then used in place of the corresponding peptides, derived from the GAG, gp120 and gp41 structural proteins.

10

Determination of oligonucleotides specific for the O group

15 Using the VAU sequence and its correlation with the MVP5180 and ANT70 sequences, oligonucleotide primers were defined which endeavor to be specific for the subgroup O in its entirety for the V3 region and the gp41 region. These primers made it possible to amplify the DUR strain and consequently constituted one solution to the amplification problem encountered. The position and the sequence of these HIV subgroup O primers are represented in Figure 13. These primers make it possible to obtain an amplification band which is visible on staining with ethidium bromide, with a single step of 30 cycles of PCR. Partial sequences were  
20 obtained:

- GAG: 513 base pairs (171 amino acids) = Seq ID No. 9
- gp120 V3 loop: 525 base pairs (75 amino acids) = Seq ID No. 10
- 30 - gp41 immunodominant region: 312 base pairs (104 amino acids) = Seq ID No. 11.

Nucleotide (Figure 15) and protein (Figure 16) comparisons of the DUR sequences with the MVP5180, ANT and VAU sequences for the O subgroup, LAI for the HIV-1  
35 consensus sequence, representative African HIV-1 MAL sequence, and CPZ for the CIV of the Gabonese

chimpanzee, show that DUR is as remote from the other published HIV-1 group (or subgroup) O strains as the latter are from each other.

5 The differences are less in the GAG region and  
maximal in the region of the V3 loop of gp120, where  
the protein comparison reaches a difference of 40%  
(Figure 16). The phylogenic trees confirm, on the one  
hand, that the DUR strain forms part of the O subgroup,  
and, on the other hand, the importance of the  
10 differences between the various O strains described,  
without, however, subtype branching emerging clearly  
(Figure 17).

Comparison of the GAG sequences:

15 On comparison of the GAG sequence obtained with  
the other two O strains published, ANT70 and MVP5180,  
as well as with the representative sequences of the M  
group (Figure 8), it was possible to observe that an O  
consensus sequence exists in several regions, which is  
20 distinct from the M consensus sequence in the same  
regions. Two hypervariable regions, which are more  
variable for O than for M, and a few point differences  
for one or the other strain may also be found.  
Nevertheless, the regions SPRT....SEGA, MLNAI....KEVIN,  
25 GPLPP....QQEQI and VGD....SPV appear to discriminate  
between the O consensus sequence and the M consensus  
sequence.

The regions QQA and LWTTRAGNP are hypervariable  
regions. The HIV-1 group (or subgroup) O DUR strain is  
30 conspicuously different in three positions with respect  
to the M and O consensus sequence (L for I and twice  
for E) and takes a specific amino acid in three  
isolated hypervariable positions, V position L9; A  
position A77; L position 110.

35 In addition, it is possible to define in the  
GAG region segments common to the O group and to the M

CORRECTED SHEET (RULE 91)

ISA/EP

group, such as SPRTLNAWVK, GSIDIAGTTST and QGPKEPFRDYVDRF.

Comparison of the sequences of the V3 loop

5 This comparative study revealed considerable differences of up to 56% for protein differences with the HIV-1 subgroup M consensus sequence, and 35 to 42% with the other HIV-1 group (or subgroup) O consensus sequences.

10 The alignments of peptide sequences in the regions of the V3 loop of gp120 and in the immunodominant region of gp41 is given in Figure 9. The sequence of the interior of the V3 loop of the DUR strain differs substantially from that of the HIV-1 subgroup M consensus sequence. It shares the motif  
15 GPMWYSM with the VAU and ANT70 strains but not with the MVP strain, which has two substitutions: R for A and R for Y.

20 The left and right parts of the rest of the V3 loop are markedly different from all the other HIVs known and do not leave it possible to imagine other cross-reactivities. Furthermore, the V3 loop of DUR is one amino acid longer than the other O sequences, which are themselves another one amino acid longer than the sequences of the HIV-1 M group.

25

Comparison of the alignments concerning the immunodominant region of gp41

30 The "mini loop" of the DUR strain, having the sequence CRGKAIC, proved to be very specific for this strain: it might constitute an epitope (see Figure 9). In addition, this sequence might be likely to be involved in the modification of the conditions of unfolding of the gp41 glycoprotein, and consequently in the infectiousness of the strain.

35 A long sequence of 11 amino acids flanking this loop on the left is identical to the VAU sequence. A

polymorphism of the DUR strain may be noted for an S or T position according to the clones analyzed.

Corresponding peptides obtained from other known retroviral strains are also represented in  
5 Figure 9.

The DUR strain also makes it possible to define an HIV subgroup O consensus sequence of the gp41 region, several sufficiently long homologous regions of which might be used. These homologous regions are,  
10 inter alia: RL'ALET, QNQQ, LWGC and CYTV ('representing a variable amino acid).

Serological correlations:

The anti-DUR antiserum does not react with the  
15 peptides of the V3 loop of the HIV-1-M consensus sequence, of HIV-1 MAL, of HIV-1 CPZ or of HIV-1 group (or subgroup) O MVP5180 but does, however, react with the peptide of the V3 loop of HIV-1-O ANT70. As regards the gp41 immunodominant region, this does not react  
20 with the "standard" HIV-1 subgroup M consensus sequence, but does, however, react, weakly but surprisingly, with the HIV-1 subgroup M right-extended consensus sequence.
